Abstract

On 27 Jan 2011 an adult *Amblyomma nodosum* tick was found attached to a domestic dog from the municipality of Colatina, state of Espírito Santo, Brazil. This is the first report of this tick species in this state and the second time it has been reported parasitizing a domestic dog in the country. For the time being, this finding should be regarded as incidental. However, more in-depth research into the hosts and ecology of *A. nodosum* is needed, since it has been associated to infectious agents that are potentially pathogenic for humans.

Keywords: Dog, *Amblyomma nodosum*, Espírito Santo, Brazil, parasitism.

Resumo

Em 17 de janeiro de 2011 um carapato adulto de *Amblyomma nodosum* foi encontrado parasitando um cão doméstico no município de Colatina, Espírito Santo, Brasil. Esta é a primeira vez que esta espécie de carapato foi descrita no Estado e pela segunda vez no país parasitando um cão doméstico. Este achado por ora deve ser considerado fortuito. Entretanto, a busca por informações adicionais sobre hospedeiros e ecologia do *A. nodosum* é recomendada uma vez que este parasito já foi associado a agente infeccioso potencialmente patogênico para seres humanos.

Palavras-chave: Cão, *Amblyomma nodosum*, Espírito Santo, Brasil, parasitismo.

Ticks are cosmopolitan ectoparasites, major infectious diseases vectors, and the geographic distribution of species is driven by both host and environmental requirements. *Amblyomma nodosum* Neumann, 1899 is a Neotropical tick species widely distributed throughout Argentina, Bolivia, Brazil, Colombia, Costa Rica, Guatemala, Guiana, Mexico, Nicaragua, Panama, Trinidad and Tobago, and Venezuela (IVANCOVICH, 1987; JONES et al., 1972; KEIRANS; BREWSTER, 1981). This tick species was first reported in Brazil by Aragão (1911) and has since then been found in several states of the country such as Goiás, Mato Grosso do Sul, Mato Grosso, Minas Gerais, Paraná, Rio de Janeiro, Rondônia, Rio Grande do Sul and São Paulo (ARAGÃO, 1936; ARZUA et al., 2005; BECHARA et al., 2002; CAMPOS PEREIRA et al., 2000; EVANS et al., 2000; LABRUNA et al., 2005; MARTINS et al., 2004). Larvae and nymphs of *A. nodosum* are mostly found on birds of several species (JONES et al., 1972; LABRUNA et al., 2007; OGRZEWAŁSKA et al., 2009a), whereas adults have a more restricted host range involving mainly members of the family

Myrmecophagidae such as the Southern Tamandua (*Tamandua tetradactyla*) and the Giant Anteater (*Myrmecophaga tridactyla*) (CAMPOS PEREIRA et al., 2000; GUGLIELMONE et al., 2003; ARZUA et al., 2005). These hosts, however, are found in all Brazilian biomes (PAGLIA et al., 2012). We herein report the case of a domestic dog with an adult *A. nodosum* tick attached to it; to the best of our knowledge, this occurrence is the first in the state of Espírito Santo and the second in Brazil. On 17 Jan 2011 an adult tick was found attached to a domestic dog in Colatina, Espírito Santo, Brazil (19° 32' 20" S and 40° 37' 51" W). The tick differed noticeably from the *Rhipicephalus sanguineus* ticks regularly found on the dog and was identified as a male *A. nodosum*, according to the taxonomic key for adult *Amblyomma* (ONOFRIO et al., 2006). The dog, a male Belgian Shepherd weighing 37 kg, belonged to one of the authors (RM) and was nine years old at the time. It lived with an adult female of the same breed and they were restricted to the owner's house and garden. The city of Colatina, population 111,188, is located in the north of the state on the banks of the Doce River (IBGE, 2010). The municipality still has a few fragments of Atlantic rainforest, its original vegetation. The dogs were occasionally taken for walks but never to forested areas. Several animals have been found in this garden, such as

toads, bats, cats, small rodents, and porcupines. Albeit never seen inside the house, opossums have been reported in that area. The owner, an amateur ornithologist, has also identified 25 different bird species in his garden. Such a variety of bird species is attracted from neighboring areas and from rainforest fragments by a mango tree (*Mangifera indica* L.) in the garden, and by various fruits the owner regularly provides for the birds. We speculate that the adult tick found on the dog was brought to the garden as an immature form on a bird as previously noted in other area (TOLESANO-PASCOLI et al., 2010). At the same time it has been described previously from dogs only once in Brazil (SABATINI et al., 2010). Birds may actually deliver ticks the other way round, picking them up in rural/urban areas (SZABÓ et al., 2008). This linking ability of birds is possibly encouraged by human activities such as, in the case reported here, the owner's bird feeding habit, which is very common human behavior. Whatever the case, bridging vectors from natural areas increases the likelihood of human and domestic animal infection. Ogrzewalska et al. (2009b) reported *Rickettsia parkeri* from *A. nodosum* ticks picked from birds. Thus, further research on the biology and ecology of this tick species is important to determine if our finding is incidental or represents an ongoing trend. Should it be proven to be a trend, awareness is warranted. In this case, existing dog-human bonds may provide a link for the transmission of infectious disease.
